

Feasible parent. For feasible $|D| \geq 3$, delete the minimum-contribution vertex $d(D)$ (ties by ID); the parent remains feasible.

Unique ownership. Traverse $C \rightarrow D = C \cup \{x\}$ only if $x = d(D)$. Thus each state has one parent and needs no visited table.

Owned path to C_1

Two paths to C_2

Traverse owned child

$\{v_5, v_6\} + v_3 \rightarrow C_2$
 $v_3 = d(C_2)$

Reject before recursion

candidate $\{v_3, v_5\} + v_6 = C_2$
 $v_6 \neq d(C_2) = v_3$

Reverse search recurses into each feasible clique once; the final containment filter returns C_1 and C_2 .
