

Deterministic minimum-contribution deletion

$$d(C) = \arg \min_{v \in C} \left(\sum_{u \in C \setminus \{v\}} \text{sim}(u, v), v \right), \quad \text{avgSim}(C \setminus \{d(C)\}) \geq \text{avgSim}(C)$$

Running example: the unique reverse paths to C_1 and C_2

Reverse DFS accepts only unique-parent insertions. The second construction of C_2 is rejected without a visited table; after strict-containment filtering, C_1 and C_2 are returned.
