

Structural MCE on Figure 1 (independent of τ)
returns the two host cliques M_1 and M_2

$M_1 = \{v_1, v_2, v_3, v_4\}$
 $\text{avgSim}(M_1) = 0.693 \geq 0.6$

Whole host is feasible
accept $C_1 = M_1$

$M_2 = \{v_3, v_4, v_5, v_6\}$
 $\text{avgSim}(M_2) = 0.427 < 0.6$

Top-Edge and vertex bounds
retain the size-3 layer

$\{v_3, v_5, v_6\}$: $0.693 \geq 0.6 \Rightarrow C_2$
other size-3 subsets: $0.373, 0.320, 0.320 < 0.6$
contained feasible pairs are skipped after C_2 is accepted

Candidate pool $\mathcal{F} = \{C_1, C_2\}$
exact deduplication and global strict-containment filtering

Output $\mathcal{R} = \{C_1, C_2\}$
